Magnetic Properties of Magnetically Anisotropic Specimens of Ferromagnetic Powders

between the texture and the specimen axis is denoted by  $\phi$ .) A dependence is established of the character of the anisotropy of magnetization curves of magnetically textured specimens, made of thin powder of the MnBi alloy, on the dimensions of the powder particles. For certain particle dimensions, a magnetization process is observed in the longitudinally textured specimens which manifests itself in the fact that saturation is reached in fields of lower intensity than the maximum values of the residual magnetization and the coercive force. On the basis of the measured magnetization curves and of particular hysteresis cycles of isotropic and magnetically textured specimens of Mn-Bi alloys of various degrees of dispersion, it was established that in fine powders a magnetic transition structure from the multi-domain to the single-domain one as well as a single-domain structure can exist. A model of the transient magnetic structure is put forward.

The Dependence of the Curves of Magnetization on the Method of Obtaining the Demagnetised State (II Zavisimost' krivykh namagnichivaniya ot sposoba polucheniya razmagnichennogo sostoyaniya)

PERIODICAL: Fizika Metallov i Metallovedeniye, 1957. Vol.V, Nr 3, pp 421-427 (USSR)

ABSTRACT: A series of powders each with a uniform particle size, lying in the range 250 to 4μ, was made from a manganese-bismuth alloy containing about 50% ferromagnetic phase. Magnetised dies were prepared from the powders by mixing them with a suitable filler, pouring into a mould, fusing at about 60°C and cooling in a magnetic field. The dies were then demagnetised either by cooling to -196°C in an alternating field, or at room temperature, by using a field of variable magnitude but constant sign to return the material to the demagnetised state from the appropriate point on one or other branch of the hysteresis loop. A part of the paper is devoted to the study of

Card 1/3

126-5-3-7/31

The Magnetic Properties of Magnetically Anisotropic Specimens Made of Ferromagnetic Powders II. The Dependence of the Curves of Magnetization on the Method of Obtaining the Demagnetised State

these 'curves of return'. Subsequent remagnetization to saturation was shown to follow a course dependent on the mode of demagnetization. Demagnetization by the first method permitted rapid remagnetization. After demagnetization at room temperature by a field of the same sign as the original magnetization, the remagnetization curve assumed a step-like form except at large particle sizes. If, however, the specimen was demagnetised by a field of opposite sign, remagnetization proceeded comparatively smoothly except at the lowest particle sizes when the curve again had a step-like appearance. An attempt is made to explain the observations qualitatively in terms of a transient magnetic structure intermediate between the single and many domained types. In presence of such a structure in the direction along the axis of the texture of magnetically anisotropic specimens, a fundamental role in the process of magnetization is played by the hysteresis in the formation and growth of remagnetization nuclei.

PERIODICAL: Fizika Metallov i Metallovedeniye, 1958, Vol 6, Nr 2, pp 229-236 (USSR)

ABSTRACT: The domain structures of powders of MnBi alloy and Co are determined from disc-shaped specimens prepared from powders of 1 to 100  $\mu$  in particle size. The Mn-Bi alloy was prepared by sintering the components at 320°C; MnBi content about 50%. The sinter was powdered and used without annealing. The Co was powdered from a piece of cast metal and annealed in vacuo at 600°C. (The method of preparing the discs is not described). Fig.1 shows the magnetization curve for an MnBi disc of particle size 25  $\mu$ , with various angles  $\phi$  between the field and texture axes. Fig.2 gives the corresponding hysteresis loops. Fig.3 shows a polar diagram of the coercive force for MnBi discs of various particle sizes (texture

Properties

axis horizontal). Fig.4 shows how the coercive force of MnBi varies with particle size for two values of  $\phi$ ; Fig.5 resembles Fig.3 but the residual magnetization is shown instead. Figs. 6 and 7 are analogous to Figs. 1 and 3 respectively, for Co powder of  $4\mu$  particle size; Fig.8 is analogous to Fig.4 and Fig.9 to Fig.5. The results are discussed in the light of the prediction that single-domain particles should occur in larger sizes the higher the anisotropy constant and saturation magnetization. The results agree with this prediction in general, but the precise shapes of the theoretical curves (shown dashed in Figs.10 and 11) are not the same as those found by experiment for MnBi of  $4\mu$  particle size. Some of these effects can be attributed to the method used for demagnetizing the MnBi powder (decreasing alternating

PERIODICAL: Fizika Metallov i Metallovedeniye, 1958, Vol 6, Nr 3, pp 420-425 (USSR)

ABSTRACT: Previous papers of this series were published in Nos 5 and 6 of the present journal (1957, Refs. 1-3). The anisotropy of the coercive force in powdered specimens of MnBi in the temperature region -196 to +20°C has been studied and results are now reported. A study was made of the magnetisation curves, recovery curves and other features of the hysteresis loops at a temperature of -196°C. It is shown that when the temperature of finely powdered specimens is reduced from +20° to -196°C, the form of the magnetic structure of the particles changes due to a reduction in the constant of anisotropy. A study of the temperature dependence of the magnetic properties of specimens of MnBi powders of different dispersity has shown that in the same

Card 1/2

SCV/126-6-3-5/32  
Magnetic Properties of Magnetically Anisotropic Specimens of Ferro-Magnetic Powders. IV. Temperature Dependence of Magnetic Properties of Powdered Specimens of the Alloy MnBi

specimens at different temperatures the existence of magnetic structure of different form may be observed. Thus, the transition structure which is present at room temperature in fine powders ( $1 - 10 \mu$ ) disappears at  $-196^{\circ}\text{C}$  and instead of it a multidomain structure is found. This is connected with the reduction in the constant of anisotropy at low temperatures. There are 6 figures, 1 table and 11 references, of which 8 are Soviet, 2 French and 1 German.

TITLE: On the Anisotropy of the Coercive Force in Magnetically Anisotropic Samples of Fine Powder (Ob anizotropii koertsitivnoy sily v magnitnoanizotropnykh obraztsakh iz tonkikh poroshkov)

PERIODICAL: Izvestiya Akademii nauk SSSR. Seriya fizicheskaya, 1958, Vol 22, Nr 10, pp 1269 - 1272 (USSR)

ABSTRACT: In the present paper the authors give a report on measurements of the coercive force of uniaxial magnetic powder produced from the following substances: Cobalt, Mn-Bi-alloy, magnetite, and iron- $\gamma$ -oxids. The angular dependence of the coercive force of various powder samples is shown in figure 1. A comparison of the curves shows that in textured samples made of magnetically uniaxial powders the angular dependences of  $H_c$  may exhibit a different character. The process of the technical magnetization in directions close to the axis of texture differs from the process of irreversible rotation. Probably this is caused by the fact

Card 1/4

On the Anisotropy of the Coercive Force in  
Magnetically Anisotropic Samples of Fine Powder

SOV/48-22-10-20/23

that the one-domain structure in the particles has not yet completely been reached. The investigation of other rules governing the magnetic properties of fine powders results in the assumption that these particles exhibit a particular domain structure (Ref 4). In one particle only one basic domain and several closing domains exist. As a consequence of this the formation, the growth, and the diminution of the closing domains plays a decisive role in the process of technical magnetization. The assumption of the existence of such a domain structure is confirmed by observations of powder patterns (Ref 5). In the case of a poly-domain structure the coercive force varies inversely as  $\cos\varphi$  (Ref 6). Therefore the coercive force increases with increasing angle  $\varphi$ . A complicated dependence of  $H_c(\varphi)$  exhibiting a maximum at a certain value of  $\varphi$  which varies between  $\varphi = 0$  and  $\varphi = 90^\circ$  may be expected. Such a regularity was observed in samples of cobalt, magnetite, and iron- $\gamma$ -oxide powder. In this case the structure apparently approximates the poly-domain structure. The magnitude of  $H_c$  of these powders,

Card 2/4

On the Anisotropy of the Coercive Force in  
Magnetically Anisotropic Samples of Fine Powder

SOV/48-22-10-20/23

however, is considerably higher than that of the respective massive substances. In the examined substances a change of the anisotropic character was not observed when the dimensions of the particles were modified. A change in the anisotropy of  $H_c$  together with the diminution of the particles was found in the investigation of magnetically anisotropic samples consisting of powder of the "low-coercive" Mn-Bi alloy. The dependence of  $H_c$  ( $\gamma$ ) found in this instance is given in figure 2. In powder of the low-coercive Mn-Bi alloys the diminution of the particles leads to a change in their magnetic structure which can be determined from the shape of the angular dependence of the coercive force. The observation results and their analysis show that in magnetically anisotropic ferromagnetics the data on the anisotropy of the coercive force besides other characteristics may give certain indications concerning the magnetic structure. There are 2 figures and 7 references, 5 of which are Soviet.

TITLE: The Temperature Dependence of Magnetic Properties of MnBi Alloy Powder Samples with Magnetic Texture

PERIODICAL: Fizika metallov i metallovedeniye, Vol 8, 1959, Nr 5,  
pp 678-684 (USSR)

ABSTRACT: The authors studied the temperature dependence of magnetic properties of samples made of the MnBi alloy powder. This alloy has a very high magnetic anisotropy constant  $K$  at room temperature (Ref 4) and a high value of the critical particle size,  $d_{cr}$  (below this size the powder particles exist in monodomain state only). On lowering of temperature the value of  $K$  falls sharply and this is accompanied by a sharp fall of the critical particle size  $d_{cr}$ , which is a function of  $K$ . It follows that on lowering of temperature the magnetic structure of MnBi alloy powders will be altered (a polydomain-monodomain transition will occur) and this change of structure will affect some magnetic properties. Consequently we can make some deductions about the structure of this magnetically uniaxial material from ✓

The Temperature Dependence of Magnetic Properties of MnBi Alloy  
Powder Samples with Magnetic Texture

the temperature dependence of its magnetic properties. The alloy was produced by heating powders of Mn and Bi together at 300 °C and its coercive force was of the order of 1000 Oe. The alloy was powdered mechanically and several fractions of the powder with particle size from 2 to 20  $\mu$  were obtained. Samples were made from each fraction by mixing the powder with a binder and by placing this mixture in a disk-like form and allowing it to set between two poles of an electromagnet. In this way magnetically textured samples were obtained whose texture axis lay along the direction of the electromagnet field. Magnetic properties were measured between 20 and -150 °C using a ballistic throw method. Samples were demagnetized at the temperature at which a particular set of measurements were carried out by a suitable constant magnetic field in the reverse direction. The angular dependences of the coercive force and residual magnetization were obtained, magnetization curves were recorded and dependence of the residual magnetization (for partial magnetization cycles) on the magnitude of  $H$ .

The Temperature Dependence of Magnetic Properties of MnBi Alloy  
Powder Samples with Magnetic Texture

powders with 30 and 3  $\mu$  particle size (curves 1 and 2 respectively). Fig 4a shows the 20 °C dependence of the relative magnetization  $I/I_s$  (curve 1) and the relative residual magnetization  $I_r/I_s$  (curve 2) on the magnetic field intensity along the texture axis (The results of Figs 4a, 4b and 4B all refer to a sample made of powder with 6  $\mu$  particle size). Figs 4b and 4B give the same dependences at -37 °C and at -60 °C. The authors draw the following conclusions from their results.

- 1) On lowering of temperature the curves representing the angular dependence of the coercive force depart more and more from the theoretical curve  $H_c(\psi)$  for a monodomain sample. This is due to a decrease of the anisotropy constant and consequent lowering of the magnitude of  $d_{cr}$  as a result of which the magnetic structure of powder particles changes gradually from monodomain to polydomain type.
- 2) At room temperature, when the anisotropy constant  $K$  and the critical particle size  $d_{cr}$  are large, the residual magnetization produced by partial magnetization

The Temperature Dependence of Magnetic Properties of MnBi Alloy Powder Samples with Magnetic Texture

cycles is close to the maximum magnetization of a complete cycle and the maximum residual magnetization is reached in the saturation field, i.e. the magnetic structure is practically monodomain. On lowering of temperature the values of  $K$  and  $dcr$  decrease and the maximum residual magnetization remains close to the saturation magnetization but is reached in fields larger than the saturation field (transition structure).

At low temperatures, i.e. when  $K$  and  $dcr$  are low, the residual magnetization is small and is reached in fields lower than the saturation field (polydomain structure).

TITLE: Certain Magnetic Properties of Manganese - Bismuth  
Alloy Powders

PERIODICAL: Fizika metallov i metallovedeniye, 1960, Vol.10,  
No.1, pp 37 ~ 41

TEXT: In earlier published work (Refs. 1 and 2) the authors detected a number of features in manganese-bismuth alloy powders which could be explained on the assumption that such powders possess a particular type of magnetic structure, a transient structure. Later on, this structure was detected experimentally by means of the powder-pattern method (Ref.3). The properties of the artificially textured powders were determined not only by the magnetic structure of the ferromagnetic particles but also by the presence of a magnetic structure, i.e. by the parallel orientation of the axes of easy magnetization of the individual particles. The authors considered it of interest to make a special study of the magnetic properties of isotropic (pseudo-crystalline) specimens from manganese-bismuth powders of various degrees of dispersion. It can be assumed in such a case that X

Certain Magnetic Properties of Manganese - Bismuth Alloy Powders

the magnetic properties of specimens are determined solely by the magnetic structure of the alloy. In the experiments, a magnetically uniaxial highly coercive MnBi alloy ( $H_c \approx 1000$  Oe) was studied. The grain size varied between 720 and 6  $\mu$  and the coercive force varied correspondingly between 1350 and 7000 Oe. The specimens were produced from powders of certain grain sizes which were carefully mixed with a binder and the mixture was poured into a mould 15 mm dia., 2 mm high. After hardening of the binder, disc-shaped specimens were obtained which consisted of randomly orientated MnBi particles interspaced with nonferromagnetic interlayers. The concentration of the MnBi powder in the specimens did not exceed 15% in volume. This quantity was sufficient for measuring the magnetic properties by means of a ballistic method but the concentration was low enough to disregard the magnetic interaction between the individual particles. Before the actual measurements the specimens were demagnetized by using three differing methods. The results of the measurements are ✓

Certain Magnetic Properties of Manganese - Bismuth Alloy Powders

plotted in Figs. 1-4. These show that the properties of the specimens were similar to those observed earlier in investigating magnetically anisotropic pseudo-single crystals of powder specimens and are due to the existence in the fine particles of a particular magnetic structure which is intermediate between multi- and single-domain magnetic structures.

Physical and Mathematical Sciences; B. M. Seolyaravich, and  
I. A. Bashkirov Ed. o Publishing House; S. Khvorakiv; Tech.  
Ed.: I. Volkchanovich.

PURPOSE: This book is intended for physicists, physical chemists,  
radio electronics engineers, and technical personnel engaged in  
the production and use of ferromagnetic materials. It may also  
be used by students in advanced courses in radio electronics,  
physics, and physical chemistry.

CONTENTS: The book contains reports presented at the Third All-  
Union Conference on Ferrites held in Minsk, Belorussian SSR.

The reports deal with magnetic transformations, electrical and  
ferromagnetic properties of ferrites, studies of the growth  
of ferrite single crystals, problems in the chemical and physi-  
cochemical analysis of ferrites, studies of ferrites having  
rectangular hysteresis loops and multicompontent ferrite systems  
exhibiting spontaneous ferromagneticity, problems in magnetic  
attraction, highly coercive ferrites, magnetic spectroscopy,  
ferromagnetic resonance, magneto-optical physical principles of  
using ferrite components in electrical circuits, etc. The Committee on Mag-  
netism, AS USSR (S. V. Vonskovskiy, Chairman) organized the con-  
ference. References accompany individual articles.

72

SOURCE: Fizika metallov i metollovedeniye, v. 15, no. 6, 1963, 839-845

TOPIC TAGS: domain structure, cobalt monocrystal, powder figure , effect of magnetic field

ABSTRACT: The domain structure variation on the basal plane of a cobalt monocrystal has been observed. This structure consists of a maze representing the outlets of the basic spontaneous magnetization domains on the basal plane of the crystal. The sample was placed into a magnetic field with intensity of about 20 000 e; it was oriented parallel to the plane (the horizontal field) and also perpendicular to the plane (vertical field). The maze pattern was obtained after the crystal cooled below the Curie point and after the sample was demagnetized by a field parallel to its hexagonal axis. It was established that powder figures consisting of star patterns are formed under the action of a magnetic field perpendicular to the axis of light magnetization. The rows of stars were oriented in the direction perpendicular to the external magnetic field. This structure was preserved also in the remnant

ABSTRACT: This paper is a short summary of investigations, conducted in the Ferromagnetic Laboratory of the Institute of Metal Physics of the Academy of Sciences, SSSR, concerning departures from homogeneity of magnetization within ferromagnetic domains. The early stages of the formation of magnetization reversal nuclei on the basal plane surface of a magnetoplumbite crystal, and their development into domains was observed by means of powder patterns. Motion pictures of this process were made, and several frames are reproduced. As the magnetizing field (perpendicular to the crystal surface) was gradually reduced from saturating values, the powder pattern,

Card 1/3

ACCESSION NR: AP4023406

initially featureless, first showed large (~0.1 mm) circular bright spots. These decreased in size, increased in number, became irregular in shape, and finally some of them could be seen to grow into twisting domains of opposite magnetization. The initial large spots revealed by the powder pattern are ascribed to "spin vortices", regions in which the spins are inclined to the surface in a circular pattern. These arise because they provide partial flux closure within the crystal, thus reducing the surface energy. As the magnetizing field decreases, the spin inclinations increase, and the disturbance penetrates more deeply into the crystal. Finally spin reversal occurs in the center of the vortex, and a reverse magnetization nucleus is formed. These nuclei grow into spike shaped domains.. If this interpretation of the observations is correct, the intersections of the wall of such a spike domain with a plane parallel to the magnetic axis should have opposite polarities; this was observed to be the case in cobalt. The domains in Co and in MnBi alloy were observed to increase in size with increasing temperature, although the saturation magnetization did not change significantly over the temperature range concerned, the crystal anisotropy decreased markedly, and no domains of closure could be found. This behavior is ascribed to spin disorientation at the higher temperatures, resulting in internal flux closure and decreased surface energy. This interpretation is supported

Card 2/3

ACCESSION NR: AP4023406

by the fact that the contrast of the domains as observed with the longitudinal Kerr effect, as well as that of the spots on the basal plane as observed with the polar Kerr effect, decreased with increasing temperature. This increase in spin disorientation with increasing temperature could be due to increasing influence of crystal imperfections as the crystal anisotropy decreases. The magnetostriction of silicon iron in the [100] direction, which should vanish in an ideal crystal, was found to depend strongly on the annealing process to which the crystal had been subjected. The less thoroughly annealed specimens showed greater magnetostriction and less perfect domain structure. This indicates departure from uniform magnetization within the domains due to crystal imperfections. It is concluded that investigation of the departure from homogeneity of the magnetization within the domains is prerequisite to a deep understanding of various properties of ferromagnetic materials.

TITLE: Magnetic properties of powders of a high-coercivity Mn-Al alloy

SOURCE: Fizika metallov i metallovedeniye, v. 22, no. 1, 1966, 39-44

TOPIC TAGS: aluminum alloy, magnesium alloy, powder metal property, magnetic property, magnetic coercive force

ABSTRACT: In order to elucidate the mechanism of the processes leading to the increase in the coercive force of Mn-Al alloy when in powdered state, the magnetic properties and phase composition of powders of a Mn-Al alloy (71 wt. % Mn) were investigated as a function of particle size (2 to 800  $\mu$ ) and heat treatment. Two series of powders were considered: the first series was obtained by pulverizing the alloy when it was in ferromagnetic state (homogenization at 1100°C with cooling in air at the critical rate of 20°C/sec, leading to the formation of the metastable ordered ferromagnetic  $\tau$ -phase); the second series was obtained by pulver-

Card 1/3

UDC: 538.245/.248

L 09006-67  
ACC NR: AP6027783

izing the alloy when it was in nonferromagnetic state (quenching in water following homogenization at 1100°C) and in this case the high-temperature paramagnetic  $\epsilon$  - phase was deformed by supercooling. The magnetic properties of the specimens were measured in fields of up to 32,000 oe by the ballistic method, while their phase composition was determined from debye-grams. Findings: for both series of powder specimens coercive force  $H_c$  increases and specific magnetization  $\sigma_{max}$  decreases with decrease in particle size. Thus, a particle size decreases from 500 to 2  $\mu$ ,  $H_c$  increases from 1300-2000 oe to 5000 oe, while specific magnetization then decreases 4-7 times for powders in the first series and about 2 times for powders in the second series. An examination of the anisotropy of coercive force in the specimens warrants the assumption that for specimens with particle size of  $< 4 \mu$  magnetic properties are primarily determined by particles with a nearly monodomain structure, and it is this that accounts for the increase in coercive force. The decrease in specific magnetization with decrease in particle size is attributed to the dis-ordering of the magnetic  $\tau$ -phase and the formation of paramagnetic equilibrium phases. Deformation of the alloy apparently leads to a decrease in the effective dimension of ordered regions of the ferromagnetic  $\tau$ -phase and to greater isolation of these regions from each other within the powder particles. This complicates the processes of magnetization reversal and increases the coercive force. The decrease in the effective size of the  $\tau$ -phase may be attributed, for the first series of powders, to local dis-ordering of the  $\tau$ -phase during pulverization of the alloy in ferromagnetic state, and for the

TITLE: Concerning the domain structure of magnetoplumbite /Report, All-Union Conference on the Physics of Ferro- and Antiferromagnetism held 2-7 July 1965 in Sverdlovsk/

SOURCE: AN SSSR. Izvestiya. Seriya fizicheskaya, v. 30, no. 6, 1966, 1030-1034

TOPIC TAGS: ferromagnetism, magnetic domain structure, single crystal, lead compound, iron compound, uniaxial crystal

ABSTRACT: The authors have employed the powder pattern technique to investigate the domain structure on the basal planes of  $PbO \cdot 6Fe_2O_3$  crystals. The investigation was undertaken because the theory of J.Kaczer and R.Gempel (Czechosl. J. Physics, B11, No. 3, 152 (1961)) does not account for the laminar domains with walls perpendicular to the magnetizing field that have been observed in uniaxial cobalt and magnetoplumbite crystals when the magnetizing field is perpendicular to the easy magnetization axis; the accumulation of more experimental data is regarded as a necessary first step toward the improvement of the theory of magnetic switching in uniaxial crystals.

Card 1/2

L 08759-67  
ACC NR. A.260291ES

The specimens were 0.68 to 2.4 mm thick plates with areas from 20 to 30 mm<sup>2</sup>. The powder patterns were observed on cleaved faces, which required no further processing. The angle  $\theta$  between the magnetizing field and the hexagonal [0001] axis could be determined within  $\pm 1^\circ$ , and the magnetizing field could be varied from zero to 20 kOe. Powder patterns were recorded in magnetizing fields of different strengths and at angles  $\theta$  ranging from 70 to 90°. Seventeen powder pattern photographs are presented and discussed. It is concluded from the observed domain structures that magnetization switching in directions nearly perpendicular to an easy magnetization axis is effected by formation and growth of nuclei of the new magnetic phase. The mechanism of nucleus formation and growth is discussed, but definite conclusions concerning that mechanism cannot be drawn from the available data. Orig. art. has: 4 figures.

TITLE: The MA-459 vibroprofiling machine

SOURCE: Tekhnologiya i organizatsiya proizvodstva, no. 1, 1966, 25-27

TOPIC TAGS: electroerosion machining, carbon electrode, graphite, vibration effect, machine tool / MA-459 machine tool

ABSTRACT: The authors describe the MA-459 vibroprofiling machine designed for forming the graphitized carbon electrodes use as the tool in electroerosion machining. This machine is much more productive than the conventional method of turning the surfaces of revolution for these electrodes on lathes and hand finishing the plane surfaces. The new machine also produces electrodes of higher quality. The machine consists of a stand, vibroprofiling head, tailstock, hydraulic feed unit and dust remover. The vibroprofiling head is designed for vibrating the master cutting tool which is fastened in a chuck. The spindle rotation is transmitted through an eccentric to this chuck which is connected to a special lever mechanism for plane parallel motion. The number of vibrations of the cutting tool is changed by using a four-speed electric drive. The profiling head has a special planetary mechanism for continuous control of the ampli-

Card 1/2

ACC NR: AP6019848

tude (radius of circular motions) of tool vibration. The tailstock is a conventional hydraulic cylinder with the piston rod connected to a second chuck for holding the electrographite stock. The hydraulic feed mechanism has a rotary pump with an electric drive. The pump provides the axial pressure necessary for machining the electrographite. The unit is equipped with a special device for periodically drawing the workpiece away from the tool to remove waste. The linear dimensions of the part being machined  $A_p$  are related to the linear dimensions of the tool  $A_t$  by the simple equation  $A_p = A_t \pm 2\Delta$  where  $\Delta$  is the total eccentricity. The plus sign corresponds the case where a depression is formed on the workpiece (a projection on the tool) while the minus sign corresponds to formation of a projection on the workpiece (a depression on the master). This profiler is approximately 25 times as productive as conventional machining. Worn graphitized carbon electrodes may be resized periodically on the MA-459 profiler using the same master tool. Title : Characteristics of vascular reactions to expansion of arteries

Periodical : Fiziol. zhur. 40, 289-294, May/Jun 1954

Abstract : Enough evidence has been collected, as result of experiments on dogs and cats, to make it evident that processes taking place in the walls of blood vessels influence their tonus and pressor reactions as well. Expansion of walls of arteries and increased blood pressure follow rapid injection of small quantity of physiological solution of sodium chloride into the central terminal of an artery. After novocain is introduced into the blood stream, pressor effect, resulting from expansion of arteries, disappears. Increased blood pressure (and expansion of arteries) is usually accompanied by decrease in size of kidneys and spleen which is in no way connected with excitation of vasoconstrictive nerve terminals. Diagrams. Eight Soviet and four non-Soviet references.

Title : An Analysis of the Mechanism of the Effect of Intra-Arterial Transfusions.

Orig Pub : Fiziol. zh. SSSR, 1956, 42, No 7, 559-564

Abstract : The authors studied the role of peripheral mechanisms in the cardio-vascular system stimulation in cases of intra-arterial blood transfusions after a complete and prolonged anemia of the central nervous system (CNS). They applied a modification of I.P. Pavlov's cardiopulmonary "preparat" [preparation ?]. Blood was circulating only in the small system and in the artificial system. In the latter, blood pressure was recorded. At various times after the beginning of the CNS anemia (from 20 up to 105 minutes), the animals were receiving

1958, 2 (3-7)

- Cerebral oedema and acute disorders of the circulation (multiple haemorrhages, per diapedesis, in the brain and viscera) after injuries of the brain or neurosurgical operations are only different forms of the same pathological process associated with a generalized disturbance in the permeability of the blood vessels. The main factor in these actions is an irritation of the vasomotor centres in the brain stem and hypothalamus. Early administration of ganglioplegics (i. v. at the operation, i. m. during 3 days after the operation) decreases the size of postoperative oedema and prevents the consecutive haemorrhages in the brain and viscera.
